THE 75TH RANGER REGIMENT is the US Army’s premier raid force. Comprising more than 3500 personnel, the regiment conducts joint special operations combat missions to include airborne, air assault, and other direct-action raids to seize key targets, destroy strategic facilities, and capture or kill enemy forces.1 Providing care to casualties during such missions is a major challenge.

See Invited Critique at end of article

Historically, approximately 90% of combat-related deaths occur prior to a casualty reaching a medical treatment facility (MTF).2,3 The combat environment has many factors that affect prehospital care, including temperature and weather extremes, severe visual limitations imposed by night operations, logistical and combat-related delays in treatment and evacuation, lack of specialized medical care providers and equipment near the scene, and lethal implications of opposing forces. Thus, a tailored approach to prehospital trauma care must be used when conducting combat operations.

Combat casualty care in World War II, the Korean War, and the Vietnam War resulted in incremental and significant improvement of civilian trauma care and systems.4 Conversely, assimilating civilian paradigms such as Advanced Trauma Life Support into the combat setting exposed deficiencies in military prehospital trauma care during conflicts in Iraq and Somalia in the early 1990s. Subsequent congressional inquiries and after-action reports led to a better understanding of profound medical differences between civilian and military environments.5-9

Emerging from these reviews and from Vietnam War casualty data analysis was an article entitled “Tactical Combat Casualty Care in Special Operations,” which presented prehospital trauma care guidelines customized for the battlefield.5 These Tac-
tactical Combat Casualty Care (TCCC) guidelines emphasized 3 objectives: (1) treat the patient, (2) prevent additional casualties, and (3) complete the mission. It then gave 3 phases of care: (1) care under fire, (2) tactical field care, and (3) casualty evacuation care. These centered on preventing the 3 major, potentially survivable causes of death: (1) extremity hemorrhage exsanguination, (2) tension pneumothorax, and (3) airway obstruction. Because TCCC guidelines diverged from accepted mainstream civilian standards for Advanced Trauma Life Support–based prehospital care, initial acceptance in the US military was slow despite a need for treatment protocols designed specifically for the tactical component of the combat environment. The TCCC guidelines have continued to evolve through a Committee on TCCC, founded in 2001 and currently reporting through the Defense Health Board to the Assistant Secretary of Defense for Health Affairs.

Tactical leaders are combat unit leaders at the battlefront. In 1998, a tactical leader and commander of the 75th Ranger Regiment, then COL Stanley McChrystal, instituted a directive for all Rangers to focus on 4 major training priorities termed the “Big Four”: (1) marksmanship, (2) physical training, (3) small unit tactics, and (4) medical training. Thus, medical readiness immediately became a highlighted area of command interest, affording the timely opportunity to establish a casualty response system integrating initial and recurrent TCCC training into programs of instruction, training exercises, and contingency planning at all levels. This complete integration of TCCC, which included TCCC training of all assigned personnel together with tactical leader assumption of responsibility for the casualty response system, was and remains an approach that is substantially different from casualty preparedness experienced throughout the rest of the Department of Defense (DoD). Although most of the US military has now included TCCC in combat medic education, they have largely continued medical training in their previous model—lacking comprehensive, all-inclusive, command-directed casualty response systems—leaving medical care to the medics, with nominal input from tactical leaders and without continuous feedback from a registry to guide performance improvements at the combat unit level.

Although the Joint Theater Trauma System and Joint Theater Trauma Registry (JTTR) were successfully implemented to oversee process improvements in military hospital-based care and outcomes, a similar global approach to military prehospital care is lacking. In addition to a comprehensive command-directed TCCC training program institutionalized prior to the onset of conflict in Afghanistan and Iraq, the regiment integrated continuous performance improvement concepts. The nucleus of this approach is a Web-based prehospital trauma registry (PHTR), the only one of its kind that collects data that have historically been difficult to capture. The PHTR is a software tool specifically designed to capture prehospital injury and treatment data with integrated features for basic analysis and instant graphing. Conceptually, the PHTR was modeled after registries required at trauma centers throughout the world but was customized for data germane to the combat casualty.

We hypothesized that training the entire fighting force in TCCC, tactical leader ownership of the casualty response system, and near-real-time feedback from PHTR data would improve outcomes for combat casualties.

METHODS

A casualty is defined in this study as a member of the 75th Ranger Regiment who sustained a battle injury for which criteria were met for award of the Purple Heart medal. Nonbattles injuries were excluded. Casualties are divided into wounded in action (WIA) and killed in action (KIA). The WIA casualties are further divided into died of wounds (DOW), returned to duty in less than 72 hours (RTD), and non-DOW and non-RTD evacuated to an MTF within 3 days. A KIA casualty is one who died prior to reaching an MTF or is dead on arrival. A DOW casualty is one who died after reaching an MTF.

Main outcomes include potentially survivable deaths and traditional combat casualty care statistics, RTD percentage, KIA percentage, DOW percentage, and case fatality rate, which are compared with DoD figures. Secondary outcomes include use of TCCC treatment protocols. Independent variables include establishment of a command-directed comprehensive TCCC program with performance improvement through the PHTR. Additional hypothesis testing was accomplished using the chi-squared test of significance set at P < .05.

More than 8000 combat missions, primarily direct-action raids, were conducted by the 75th Ranger Regiment in Afghanistan and Iraq between October 1, 2001, and March 31, 2010. Prehospital casualty and treatment data from these missions were collected directly from medics, most within 72 hours of an event, on a Ranger Casualty Card, adopted later as DA Form 7656. Data were then entered into the PHTR and cross-referenced with other operational sources to include Purple Heart packets, casualty trackers, mission logs, medical records, JTTR data, and Armed Forces Institute of Pathology autopsy data. Medical and tactical leaders scrutinized casualties for opportunities to improve care through formal investigation of data from the PHTR, JTTR, and Armed Forces Institute of Pathology. Process of care was analyzed for appropriateness and effectiveness. Casualties and treatments were critically analyzed within the context of the tactical mission. Casualties were followed to final disposition. Deaths were analyzed in detail for performance improvement opportunities. Comparisons with similar military prehospital data could not be made, as they do not exist.

Institutional review boards at the Texas A&M Health Science Center and the US Army Medical Research and Materiel Command provided approval to conduct this study.

RESULTS

Battle injury data were collected from October 1, 2001, to March 31, 2010, for Operation Enduring Freedom in Afghanistan and from March 15, 2003, to March 31, 2010, for Operation Iraqi Freedom. Casualty cards were available for 74% of casualties, JTTR data for 78% of evacuated casualties, and Armed Forces Institute of Pathology autopsy data for 100% of fatalities. Demographic, injury, and outcome data were obtained through other operations sources for the 26% of casualties without completed cards. By combining data sources, 100% of casualties had adequate data available for analysis. Casualties who did not seek prehospital care and medics limited by the mission accounted for missing casualty cards.
Of the 419 casualties incurred, including 239 (57%) from Operation Iraqi Freedom and 180 (43%) from Operation Enduring Freedom, 387 (92%) survived (Figure 1). All casualties were male, with age at time of injury ranging from 18.9 to 52.9 years. Infantrymen were most frequently injured (86%), followed by medical personnel (5%) and artillerymen (3%). Overall demographic characteristics were reflective of other military combat regiments and brigades.

Mechanisms of injury included explosions—improvised explosive device (IED) and non-IED—resulting in blast, ballistic, and blunt trauma as well as gunshot wound injuries and aircraft and ground vehicle blunt trauma injuries. Non-IEDs were the most frequent cause of injury (43%). Gunshot wound injuries accounted for half of all deaths (Figure 2). None of the 32 deaths resulted from the 3 major potentially survivable causes of death (extremity hemorrhage exsanguination, tension pneumothorax, and airway obstruction) defined in the literature.2,3,6,29-31 One casualty with potentially survivable extremity wounds died of post-surgical complications following evacuation.

Although the DoD does not have a process to systematically evaluate potentially survivable deaths, the regiment’s 3% rate (1 in 32) is significantly lower than the 24% rate (232 in 982) previously reported for a subset of US fatalities from Operation Enduring Freedom and Operation Iraqi Freedom ($\chi^2 = 6.2$, $P = .01$).31 Benchmark statistics for RTD, KIA, DOW, and case fatality rate provided in Table 1 and Table 2 depict decreased combined theater and Operation Iraqi Freedom KIA and DOW rates for the 75th Ranger Regiment compared with US ground troop rates for the same period ($P < .05$). The RTD rates were lower in surviving Rangers, likely signifying increased severity of wounding.

Most interventions were for hemorrhage control (Table 3), 26% of which were applied by nonmedical personnel. A total of 89 tourniquets were applied to 66 casualties, with no resultant complications, which is consistent with cited safety.32,33 Nonmedical personnel accounted for 42% of tourniquet applications. Of casualties with tourniquets, almost all reached the next level of care (95%) and ultimately survived (94%). Only 16% of these survivors had injuries resulting in limb amputations, 8 with 1-limb amputation (7 below the knee and 1 below the elbow) and 2 with 2-limb amputations (3 above and 1 below the knee). A total of 37 hemostatic dressings were applied to 30 casualties, with 71% reaching the next level of care and ultimately surviving.

Fewer than 10% of casualties received advanced airway or breathing interventions (Table 4). Advanced airway procedures (intubation or cricothyroidotomy) were performed in 14 casualties in extremis, of whom 4 reached a hospital alive. Attempted intubations were converted to successful surgical airways in 3 instances, but these casualties died of their wounds prior to reaching a hospital. Advanced breathing interventions (thoracentesis or thoracostomy) were provided to 20 casualties, of whom 59% survived to reach the next level of care and 50% ultimately survived. No casualties died of airway obstruction or tension pneumothorax.

Prehospital vascular access was obtained for 90 casualties (Table 5), of whom 61% received intravenous fluid and 39% received vascular access only. Of casualties resuscitated with intravenous fluid, almost all reached the next level of care alive (96%) and ultimately survived (93%), with 64% receiving crystalloid, 27% colloids, and 9% both. Of casualties who received vascular access only, 91% reached the next level of care alive and also ultimately survived. Sternal intraosseous access was used in 1 casualty.

Consistent with evolving TCCC guidelines,6,13-17 trends over time show a decrease in intravenous fluid use and an increase in obtaining vascular access only for casualties in shock or requiring intravenous medications.

Prehospital antibiotics and analgesics were provided to reduce risk of infection and pain syndromes.6,13-17 A total of 113 casualties received antibiotics, including 81 who self-administered oral combat wound pill packs consisting of a fluoroquinolone and two analgesics (acetaminophen and either celecoxib or meloxicam).13-15,3428 Who received parenterally administered antibiotics (75% ertapenem sodium and 25% a cephalosporin), and 4 who received both. No adverse reactions to antibiotics were reported. Of all casualties, 25 (6%) developed an infection during hospitalization. Additionally, 6% of casualties who did not receive prehospital antibiotics developed an infection, compared with 4% of those who did receive prehospital antibiotics. Most casualties with an infection (80%) did not receive prehospital antibiotics. Almost all infections (96%) occurred after evacuation from the combat theater, and nearly half (48%) were cultured as Acinetobacter. One casualty progressed to sepsis but survived. No casualties were categorized as DOW from infection.

A total of 146 casualties received prehospital analgesics other than combat wound pill packs. These include...
82 casualties who were administered oral transmucosal fentanyl citrate, 23 who received morphine sulfate, 27 who received both, and 14 who received other analgesics (hydromorphone hydrochloride, hydrocodone bitartrate, ketorolac tromethamine, or ibuprofen). Of the 50 casualties who were administered morphine, 30 (60%) received it intravenously and 20 (40%) intramuscularly. Only 1 casualty, who received oral transmucosal fentanyl and morphine, was noted to have other-than-minimal adverse effects.36

Figure 2. The 75th Ranger Regiment casualties (n=419) (A) and fatalities (n=32) (B) by mechanism of injury between October 1, 2001, and March 31, 2010. Due to rounding, percentages may not total 100%. GSW indicates gunshot wound; IED, improvised explosive device. a Of casualties who died of GSW injuries, 44% were from coronal trajectory transthoracic wounds, 31% were from sagittal trajectory transcranial wounds, 13% were from coronal trajectory transthoracic and neck wounds, and 6% were from sagittal trajectory extremity wounds. b Of casualties who died of IED injuries, all had massive head and extremity wounds and 90% also had massive torso wounds. c Non-IED explosives include mortars, grenades, and rocket-propelled grenades. Of casualties who died of non-IED explosive injuries, all had massive torso and extremity wounds and 33% also had massive head wounds. d Blunt trauma includes nonblast combat-related aircraft and vehicle incidents. Of casualties who died of blunt trauma injuries, all had massive head, torso, and extremity wounds with a crush component.

b Total WIA = RTD + [non-DOW and non-RTD] + DOW.

The Rangers are the only DoD force that has institutionalized a unitwide casualty response system using the following integrated 3-part approach: (1) TCCC training for all personnel, (2) tactical leader ownership of the prehospital casualty response system, and (3) use of PHTR data to rapidly update TCCC protocols, force health protection, and training. Focused on increasing battlefield casualty survival, this approach enables performance improvements through data-driven multidisciplinary review and consensus regarding best practices.

Because approximately 90% of all battlefield deaths occur prior to the casualty reaching an MTF,2,3 process improvements directed toward prehospital care have the best opportunity to improve survival from combat injury. Data on potentially survivable deaths from the Vietnam War suggest that 60% were from extremity hemorrhage exsanguination, 33% from tension pneumothorax, and 7% from airway obstruction.2,29–31 Despite widespread recognition of these causes and overall US military case fatality rate reduction from 19.1 in World War II to 15.8 in the Vietnam War to 10.3 in current con-
flicts described in this study, these 3 major causes of death continue to be present in Afghanistan and Iraq.26,30,31 Holcomb et al30 identified opportunities to improve care in 12 of 82 deaths (15%) among Special Operations Forces. In a review of 982 deaths, Kelly et al31 reported 24% of deaths as potentially survivable, with opportunity to improve care equally distributed between prehospital and hospital settings. Although it cannot be absolutely quantified as resulting from their casualty response system, an overall case fatality rate of 7.6 coupled with the elimination of prehospital preventable deaths validates to a notable degree the Ranger training approach (Table 6).

Training for T.C.C.C. was initiated by the Rangers in 1997 and formed the basis for 2 programs of instruction, Ranger First Responder (RFR) and Casualty Response Training for Ranger Leaders.12,16-18 Because care under fire must be simple, direct, and conditioned into the provider, RFR emphasizes repetitive hands-on application of T.C.C.C. lifesaving skills incorporated into realistic scenario-based learning. Everyone on the battlefield, not just medics, has the potential to be a casualty or to be the first person to encounter a casualty; thus, RFR is mandated for all personnel in the regiment regardless of their role.18 This concept is best illustrated by the fact that 26% of hemorrhage control interventions in this study, including 42% of tourniquets, were applied by nonmedical personnel at the point of wounding, probably decreasing the necessity for additional prehospital resuscitation and certainly contributing to no preventable deaths due to extremity hemorrhage exsanguination.

Because the tactical commander manages all resources dedicated to preparing for and completing a mission, it is this nonmedical leader who is ultimately responsible for the prehospital casualty response system. This concept differentiates RFR and Casualty Response Training for Ranger Leaders from other medical programs. The goal is to educate all on the operational con-
sequences of a casualty and how to mitigate adverse outcomes for both the casualty and the mission. A key underpinning of this training is the use of the term casualty response rather than medical training, as it imparts a collective requirement for the entire fighting force to take action as with any other battle drill. When a casualty occurs on a mission, the event is a tactical problem to be solved and not just an isolated medical issue. Casualty battle drills are embedded into small unit tactics and tactical training exercises. Realism is maximized

by introducing the turbulence of casualty scenarios into the natural flow of tactical training. Mastery of this training instills confidence in the casualty response system, increasing unit morale and cohesion as all come to realize that the best possible care will be provided promptly by fellow soldiers on the battlefield, thus putting medical capability on par with fighting capability.

Medical training in the DoD is not consistent among the services and between units. In the US Army, a centralized 16-week medical course is used to initially train combat medics. Thereafter, sustainment medical training, tactical training, and employment of combat medics are decentralized and the responsibility of the individual line commander. Tactical line commanders who understand the requirements and importance of the casualty response system will provide the time, training, and equipment necessary to ensure that medical personnel, and ultimately all assigned personnel, are sufficiently prepared to receive combat casualties. This is not the norm, however, as many do not realize this responsibility or recognize the operational importance of casualty care.

A standardized Ranger medic training pathway was initially established in 1998. This pathway was refined to include Emergency Medical Technician Paramedic or 26-week Special Operations Combat Medic training followed by recurrent sustainment, assessment, and validation training that maximizes use of human patient simulators, live tissue training, realistic trauma lanes, and major metropolitan trauma center rotations. To provide a foundation for medic knowledge, the first official Ranger Medic Handbook was distributed throughout the regiment in 2001. This TCCC-based handbook, updated periodically, provides medics with guidelines, protocols, and procedures for optimizing prehospital care.

A 4-week Emergency Medical Technicians Basic program was mandated for 1 in 10 nonmedics as a means to bridge the gap between RFRs and Ranger medics. Recurrent sustainment training includes the Prehospital Trauma Life Support course, as this course has evolved to include military and TCCC-based protocols and procedures. This Emergency Medical Technicians Basic program not only expanded medical capabilities, it also created more medically knowledgeable tactical leaders as they advanced through the leadership ranks.

In the regiment, it is now common and expected for nonmedical personnel to rapidly and accurately manage life-threatening extremity hemorrhage. This impressively improves tactical leader awareness and responsibility for their casualty response system. Tactical leaders now hold themselves accountable for casualties and casualty response training through self-assessment and unit status reports. Demonstrated medical proficiency is regarded to be as important as weapon proficiency. Well-informed nonmedical leaders may ultimately play the most important role in reducing preventable death on the battlefield. In fact, intensive training, contingency planning, and an appropriate tactical response to casualty scenarios may have saved more lives than the medical interventions themselves.

Prehospital record keeping and the availability of such data are notoriously challenging on the battlefield. In 2001, the regiment began work on a minimalistic data set captured through a Ranger Casualty Card collection program. The template for this card was adopted by the US Army in 2009 as DA Form 7656 TCCC Casualty Card. With direct support from Congress, funds were allocated for a combat trauma registry modeled after trauma registry concepts developed during the past 40 years in the civilian sector. The hospital effort centered on inpatient medical treatment facilities through the JTTR and the prehospital effort centered on a tactical unit through the PHTR.

The primary purpose of the PHTR is to provide tactical leaders and medical care providers with near-real-time trends, reports, and analysis for lessons learned, quality assurance, and performance improvements designed to immediately reduce morbidity and mortality on the battlefield. Commanders quickly make data-based decisions to optimize casualty response and force protection, resulting in rapid treatment protocol modification and body armor evolution. Resultant directed procurement of medical devices and personal protective equipment is data driven, peer reviewed, and cost-effective.

Historically, war and conflict have prompted advances in both individual techniques and effective systems to improve trauma care. The current war is no exception. Prehospital advances implemented by TCCC have improved the probability that casualties will arrive at the hospital alive so they can benefit from the trauma care system now in place. However, not all opportunities have been realized. The remaining challenge is to refine performance improvements and best practices through systemwide prehospital data collection.

The TCCC guidelines represented a paradigm shift away from civilian prehospital care practices. The casualty response system described in this study is also a shift away from traditional US military practices. Despite the lethality of modern-day warfare, the 75th Ranger Regiment’s implementation of a comprehensive casualty response system sustained by focused training directed by tactical leaders using data from a unit-based PHTR has resulted in historically low casualty rates for a frontline unit of its type, to include virtual elimination of preventable combat death. This approach has been recommended by the Defense Health Board for implementation by combatant units throughout the DoD.

Performance improvements in prehospital care are actively migrating from the current battlefield to civilian practice. Implementing these initiatives in concert with detailed documentation and analysis may have profound implications for civilian prehospital trauma training, care, and preventable death, especially in light of the fact that equivalent epidemiological studies on potentially survivable death from trauma in the civilian prehospital environment are sparse, and none have documented a pathway for successful elimination of preventable death. A civilian prehospital system that integrates first responder skills throughout a community and enacts performance improvement through a registry may also eliminate preventable death.

This report was approved for public release by the US Army Special Operations Command Operational Security Office and the Public Affairs Office on October 8, 2010.

Previous Presentation: The abstract was presented at the 2011 Combat Trauma Innovation Conference; January 18, 2011; London, England.

Additional Information: This article is dedicated to SFC Marcus V. Muralles, a former 75th Ranger Regiment Special Operations Combat Medic who was killed in action while serving with the 160th Special Operations Aviation Regiment in Afghanistan on June 28, 2005, and SGT Jonathan K. Peney, a Special Operations Combat Medic who was killed in action while serving with the 75th Ranger Regiment in Afghanistan on June 1, 2010.

Additional Contributions: We acknowledge the Texas A&M Health Science Center Rural and Community Health Institute for their collaboration on the PHTR; the JTRT and the Armed Forces Institute of Pathology for providing casualty outcome data; and all senior Ranger Special Operations Combat Medics whose practical experiences and perspectives contributed immeasurably to the development and implementation of Ranger medical training programs and the PHTR. Most importantly, we especially recognize the sacrifices of the casualties depicted in this article as well as their fellow Rangers who provided care to them.

Innovative Leadership of Casualty Care

A lan Keith of Genetec stated, “Leadership is ultimately about creating a way for people to contribute to making something extraordinary happen.” Kotwal et al report on a remarkable commitment to casualty care by the 75th Ranger Regiment. The Rangers coupled a novel approach to combat casualty care with modern continuous process improvement. When this was applied in battle, the process resulted in the lowest mortality rate, especially the preventable mortality rate, in the Armed Forces.

The authors highlight that the transference of Advanced Trauma Life Support from civilian settings into combat exposed significant deficits in battleground prehospital care back as far as the 1993 fighting in Somalia. The deficiencies of civilian Advanced Trauma Life Support were quickly addressed. In 1996, the TCCC guidelines were published; they took into account issues unique to battle such as prevention of additional casualties, mission completion, and the tactical challenges of evacuations under fire and focused medically on the 3 major causes of preventable death: hemorrhage from extremity wounds, tension pneumothorax, and airway problems. Unfortunately, the military as a whole was slow to adopt the TCCC guidelines, and only the Special Operations units implemented them quickly.

The next leadership step was the inclusion of medical training as one of the “Big Four” priorities for every member of the 75th Ranger Regiment. Among the Rangers, 100% were trained as first responders, 10% as emergency medical technicians, and 3% as combat medics. This meant that every member of the regiment was responsible for casualty care of his fellow soldiers, and battle commanders also had medical knowledge and training that could be taken into consideration when making tactical decisions. This is different from the majority of the Armed Forces where medics are relied on heavily for tactical decisions. This is different from the military——it has been previously shown in the challenging low-resource civilian environments of Cambodia, Vietnam, Iraq, and Afghanistan, where the scourge of land mines kill and injure civilian populations. Through the leadership of the Trauma Care Foundation and the Tromso Mine Victim Resource Center, programs exist to successfully train lay village workers through ‘village universities’ as first responders for injuries. These civilian injuries share some similarities with the battlefield in that prevention of other casualties must be ensured because the victims are lying in a minefield and extremity hemorrhage and airway issues are common. As opposed to US combat operations, there are unique low-resource challenges such as minimal local hospital resources leading to prolonged prehospital transport times. Even with these challenges, Husum et al were able to show a reduction in the mortality rate from 40% to 14.9% with a mean evacuation time of 5.7 hours in a prospective study based in North Iraq and Cambodia from 1997 to 2001. The measurable success of programs that teach nonmedical personnel in prehospital care and its outstanding effects on outcomes are a lesson that I think is applicable to both military and low-resource civilian environments. My hope is that these data will serve as an impetus for the remainder of the Armed Forces to adopt these lifesaving strategies.
